

Effective Visualization

Effective visualization

Implies saying the **truth** about the data

Tufte presents a lot of commented examples in his book:

Tufte, E., *The Visual Display of Quantitative Information*, Graphics Press, 1983

There are methods to evaluate visualizations that should be used along the process of creating a visualization

https://infovis-wiki.net/wiki/Lie_Factor

this example has several problems:

Legends have a constant size in one side and variable in the other

This line, representing 18 miles per gallon in 1978, is 0.6 inches long.

This line, representing 27.5 miles per gallon in 1985, is 5.3 inches long.

In roads, future usually lies in front, not behind

- Perception varies among people and with

- context

- experience

(Tufte, 1983)

- How do we know that the visual image represents the underlying numbers?
- One way to try to answer these questions is to conduct experiments on the visual perception of graphics

**I think I see that area B
is 3.14 times bigger than
area A. Is that correct?**

(Tufte, 1983)

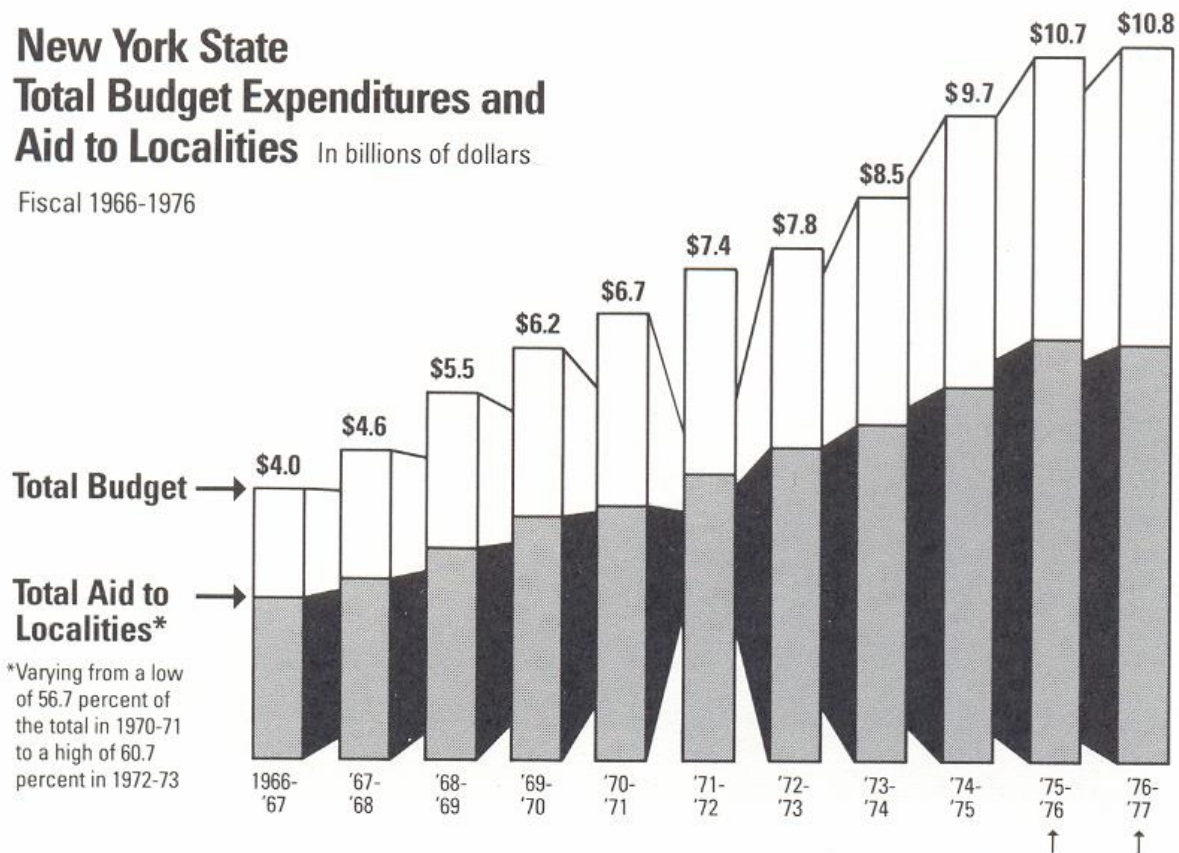

- What to do when we want to represent data in a graphic ?
- According to Tufte there are two fundamental principles to get graphical integrity:
 - represent numbers, as physically measured on the surface of the graphic itself, **directly proportional** to the numerical quantities represented
 - Clear and thoroughly **label** to defeat graphical distortion and ambiguity

Note:

Visual representations must be **tested** as to their efficiency and efficacy for the target users to perform their tasks

Effective visualization: anatomy of poor examples

Another example having several issues:

These three parallellipeds have been placed in an optical plane in front of the other eight, creating the image that the newer budgets tower over the older ones

Horizontal arrows provide emphasis, Encourage the impression that recent years have shot up from a small stable base

*Varying from a low of 56.7 percent of the total in 1970-71 to a high of 60.7 percent in 1972-73

Arrows pointing straight up emphasize recent growth

Leaving behind the distortion

we have a calmer view:

Two statistical lapses also bias the chart :

- Population increased 10%
- there was substantial inflation

Final result →

Effective Visualization: another poor example

Consider the following questions to be answered based on a data set:

- Which area of study grew the most?
- Which area of study decreased the most?
- How did Humanities behave?
- How many areas of study are increasing and how many are decreasing?

These pie charts have several issues:

- Chart type
- Time direction
- 3D effect
- Exploded slices and n. of slices
- Color usage ...

The “graphenstein” (Camões, 2016)

A better way to answer the questions and provide insights from the same data:

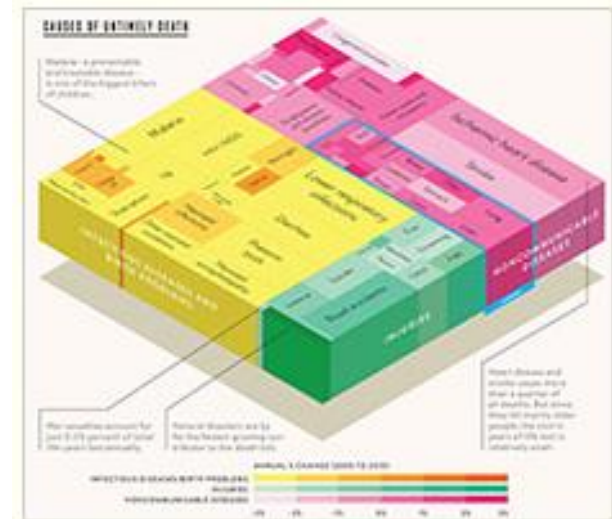

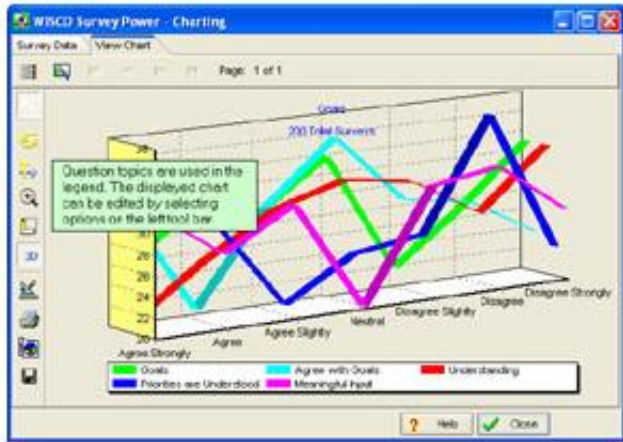

(Camões, 2016)

Hard-to-spot variations in the pie charts are now obvious:

- Line slopes display changes clearly
- color is used to make the chart easier to read.

Effective visualization: more poor examples analyzed

Remember: There are methods to evaluate visualizations that should be used along the process of creating a visualization

Color may help a lot in some tasks

...

How many cherries?

It may hinder if not properly applied ...

It should be applied sparingly and carefully
should serve a purpose, be clear, and not distract

Common pitfalls of color use

- **Encoding too much or irrelevant information**

(the coloring of states serves no purpose, colors are over saturated; it is distracting)

- **Using non-monotonic color scales to encode data values**

(The rainbow color scale is not an appropriate to visualize continuous data values; it tends to emphasize arbitrary features of the data)

- **Not designing for color-vision deficiency**

Color Blindness

- The most common type is deuteranopia (“daltonism”) (affects ~10% of men; is residual in women)
- There are color blindness simulators and colorblind-friendly color scales

Normal vision

Deuteranopia

Tritanopia

Drag and drop or paste your file in the area below or: Nenhum ficheiro selecionado

Trichromatic view: Normal
Anomalous Trichromacy:
 Red-Weak/Protanomaly
 Green-Weak/Deuteranomaly
 Blue-Weak/Tritanomaly

Dichromatic view:
 Red-Blind/Protanopia
 Green-Blind/Deuteranopia
 Blue-Blind/Tritanopia

Monochromatic view:
 Monochromacy/Achromatopsia
 Blue Cone Monochromacy

Use lens to compare with normal view: No Lens Normal Lens Inverse Lens

Guidelines to use color

- Design first in black and white; then color apply sparingly and carefully
- Use direct labeling instead of colors when you need to distinguish between more than about eight categorical items
- Avoid large filled areas of overly saturated colors. They make it difficult for the reader to carefully inspect the figure
- To make sure figures work for people with cvd, don't just rely on specific color scales. Instead, test figures in a cvd simulator
- Do not use blue to color small objects (will be difficult to see)

<https://clauswilke.com/dataviz/color-pitfalls.html>

- Visualizations produced to be used by many users should be evaluated to improve their effectiveness

- There are several methods that can be used to evaluate

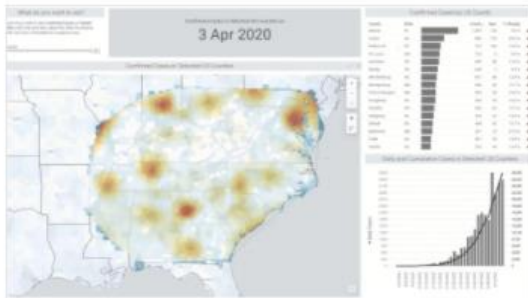

At least review your visualizations considering the questions they should help users to answer and ask some target users to use them and provide feedback... Then, improve your visualizations!
