

A Recursive Construction of the Regular Exceptional Graphs with Least Eigenvalue -2

I. Barbedo, D. M. Cardoso, D. Cvetković, P. Rama, S.K. Simić*

Abstract.

In spectral graph theory a graph with least eigenvalue -2 is exceptional if it is connected, has least eigenvalue greater than or equal to -2 , and it is not a generalized line graph. A (κ, τ) -regular set S of a graph is a vertex subset, inducing a κ -regular subgraph such that every vertex not in S has τ neighbors in S . We present a recursive construction of all regular exceptional graphs as successive extensions by regular sets.

Mathematics Subject Classification (2010). Primary 05C50; Secondary 06A06.

Keywords. Spectral graph theory, exceptional graphs, posets.

1. Introduction

Let $G = (V(G), E(G))$ be a simple graph, where $V(G)$ denotes the nonempty set of vertices and $E(G)$ the set of edges. It is assumed that G is of order n , i.e. $|V(G)| = n$. An edge of $E(G)$, which has the vertices i and j as end-vertices is denoted by ij . When there is an edge between the vertices i and j we say that these vertices are adjacent. The neighborhood of a vertex $u \in V(G)$, $N_G(u)$, is the set of vertices adjacent to u , that is, $N_G(u) = \{v \in V(G) : uv \in E(G)\}$. The degree of vertex u is the cardinality of its neighborhood. A graph G is r -regular (or regular of degree r) if each vertex of G has the same degree r .

Throughout the paper, A_G denotes the adjacency matrix of G , that is $A_G = (a_{ij})_{n \times n}$, where $a_{ij} = 1$ if $ij \in E(G)$ and $a_{ij} = 0$ otherwise. The eigenvalues of the graph G are the eigenvalues of its adjacency matrix, here ordered such that $\lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_n$. A detailed treatment of graph eigenvalues can be found in [6].

Rama were partially supported by Portuguese funds through the CIDMA - Center for Research and Development in Mathematics and Applications, and the Portuguese Foundation for Science and Technology (“FCT-Fundação para a Ciência e a Tecnologia”), within project PEst-OE/MAT/UI4106/2014.

A pair (X, \mathcal{B}) is a $1 - (v, l, \lambda)$ design, if X is a set with cardinality v and \mathcal{B} is a family of b subsets of X with cardinality l , called blocks, and each element $x \in X$ lies in exactly λ blocks. The incidence matrix B of a $1 - (v, l, \lambda)$ design is the $v \times b$ matrix with ij -entry equal to 1 if $x_i \in B_j$ and 0 otherwise. Alternatively, a $1 - (v, l, \lambda)$ design (X, \mathcal{B}) can be represented by a semi-regular bipartite graph with parameters (v, b, λ, l) , i.e. by a bipartite graph with v vertices of degree λ in one colour class, and b vertices of degree l in another colour class.

A connected graph with least eigenvalue greater than or equal to -2 is either a generalized line graph (with line graphs included), or an exceptional graph (see, e.g., [9]). According to [9, Proposition 1.1.9], a regular connected generalized line graph (see definition, e.g., in [9, Section 1.1]) is either a line graph or a cocktail party graph (a regular graph on $2k$ vertices of degree $2k - 2$). A graph is said to be *exceptional* if it is connected, has least eigenvalue greater than or equal to -2 , and it is not a generalized line graph. It is known [8] that an exceptional graph has at most 36 vertices, with vertex degrees at most 28. There are exactly 187 regular exceptional graphs. They are divided into three subsets (to be defined later) called *layers*. These graphs can be constructed [1, 7, 9] using different techniques. A comprehensive survey of problems on graphs with least eigenvalue at least -2 , including exceptional graphs, can be found in [9].

A vertex subset $S \subseteq V(G)$ of the graph G is a *stable (or independent) set* if no pair of vertices in S is connected by an edge. A stable set with maximum cardinality is a maximum stable set.

Given a graph G , a partition $\pi = (V_1, \dots, V_r)$ of the vertex set of G is an *equitable partition*, if for any pair $i, j \in \{1, \dots, r\}$ there exists $d_{ij} \in \mathbb{N}_0$ such that for all $v \in V_i$ $d_{ij} = |N_G(v) \cap V_j|$, that is, the number of neighbors that a vertex of V_i has in V_j is independent of the choice of the vertex in V_i .

A (κ, τ) -regular set S of a graph G is a vertex subset which induces a κ -regular subgraph such that every vertex not in S has τ neighbors in S . If G is a regular graph, then a (κ, τ) -regular set S defines an equitable bipartition in G .

The (κ, τ) -regular sets appeared first in [13], under the designation of eigen-graphs, and also in [12], in both cases in the context of strongly regular graphs and designs. Later on, the (κ, τ) -regular sets were investigated in the general context of arbitrary graphs [3, 4, 5].

The aim of this paper is to present a recursive construction of all regular exceptional graphs based on the new (κ, τ) -extension technique suggested in [2]. It recursively generates the families of regular exceptional graphs along with a partial order relation among them, and this is represented by its Hasse diagram.

In Section 2 we describe the (κ, τ) -extension technique of a regular graph G by a regular graph H , and also the partial order relation that arises. The process of extending a graph is reduced to the construction of the incidence matrices of a 1-design (or an appropriate bipartite semi-regular graph).

In Section 3 we propose a technique to construct the regular exceptional graphs, by $(0, 2)$ -extensions in the case of 1st and 2nd layer, and by $(1, 3)$ -extensions in the case of 3rd layer and using the fact that all these graphs admit an equitable

partition. In each case we describe how to construct the incidence matrices of the 1-design desired, stating some proprieties. In addition, we also propose an algorithm to construct the regular exceptional graphs in each layer.

In Section 4 we describe, in more details, the computational results that were obtained by the algorithm for the three layers.

The Appendix contains for each regular exceptional graph the list of other regular exceptional graphs with a minimal number of vertices in which it is contained as a proper induced subgraph.

2. Construction of regular graphs by (κ, τ) -extensions

Let G be a $(p - \tau)$ -regular graph of order n_1 (with $\tau > 0$) and H a κ -regular graph (with $\kappa < p$) of order n_2 . Our aim is to obtain a p -regular graph $H \oplus G$, of order $n_2 + n_1$, such that each vertex in G has τ neighbors in H , and each vertex in H has exactly $p - \kappa$ neighbors in G (hence $V(H)$ is a (κ, τ) -regular set in $H \oplus G$). The procedure that generates the graph $H \oplus G$ from G is called a (κ, τ) -extension of G of size n_2 . This construction is possible if we can define a family, \mathcal{S} , of n_1 subsets in $V(H)$, called *blocks*, each of them with cardinality τ , so that each $v \in V(H)$ is in exactly $p - \kappa$ blocks of \mathcal{S} , that is, $(V(H), \mathcal{S})$ is a $1 - (n_2, \tau, p - \kappa)$ design. Note that there is a $1 - (n_2, \tau, p - \kappa)$ design if and only if $\frac{n_1}{n_2} = \frac{p - \kappa}{\tau}$. Hence the adjacency matrix of $H \oplus G$ is given by

$$\begin{bmatrix} A_H & B \\ B^T & A_G \end{bmatrix},$$

where A_H and A_G are the adjacency matrices of H and G , respectively, and B is the incidence matrix of a $1 - (n_2, \tau, p - \kappa)$ design, that is, each column of B is the characteristic vector of a block. Further on, we shall use graph theoretical terminology and consider the corresponding semi-regular bipartite graphs.

The (κ, τ) -extension of a regular graph G by a regular graph H to obtain another regular graph $H \oplus G$, can be applied recursively to generate a sequence of regular graphs. Considering the $(p - \tau)$ -regular graph G and the κ -regular graph H described above, starting with $G_0 = G$, we can generate a set \mathcal{F} of $((p - \tau) + m\tau)$ -regular graphs, G_m , of order $n_1 + m n_2$, where each G_m is obtained by a (κ, τ) -extension of G_{m-1} ($m \geq 1$). Consequently, we can define the following partial order relation \preceq on \mathcal{F} , or on any set of graphs.

Definition 2.1. Given κ, τ, s , if G, G' are regular graphs, then $G \preceq G'$ if and only if G' can be obtained from G by a sequence of zero or more (κ, τ) -extensions of size s .

3. Construction of regular exceptional graphs

The set of regular exceptional graphs is partitioned into three layers according to degree r and order n [9, Theorem 4.1.5]. Any such graph is in the 1st, 2nd or 3rd layer, if the following holds, respectively:

- (i) $n = 2(r + 2) \leq 28$,
- (ii) $n = \frac{3}{2}(r + 2) \leq 27$ and G is an induced subgraph of the Schläfli graph,
- (iii) $n = \frac{4}{3}(r + 2) \leq 16$ and G is an induced subgraph of the Clebsch graph.

There are 163 graphs in the 1st layer, 21 in the 2nd layer and 3 in the 3rd layer, i.e. 187 in total.

The regular exceptional graphs are completely described in Table A3 in [9, pp. 213-227]. As in [9], regular exceptional graphs are denoted by numbers 1 – 187.

Let \mathcal{L} be the set of regular graphs whose least eigenvalue is greater than or equal to -2 . Hence \mathcal{L} includes all regular exceptional graphs. We shall consider subsets $\mathcal{L}_1, \mathcal{L}_2, \mathcal{L}_3$ of \mathcal{L} in which the ratio $\frac{n}{r+2}$ (n the number of vertices, r the degree) is the same as in layers 1, 2, 3, respectively. Hence, each layer is a subset of the corresponding set $\mathcal{L}_1, \mathcal{L}_2$ or \mathcal{L}_3 .

Let G be a regular graph of degree r and order n . Let $\alpha(G)$ be the size of a maximum stable (or independent) set of G and λ_n its least eigenvalue. Then

$$\alpha(G) \leq \frac{-n\lambda_n}{r - \lambda_n}.$$

This inequality is known as the Hoffman inequality although A.J. Hoffman never published it. For some bibliographical details related to this bound see [2].

In [2] it is noted that in the case of regular exceptional graphs of the 1st and 2nd layers, the Hoffman upper bound is attained and is equal to the cardinality of a maximum stable set, which is 4 and 3, respectively. This observation has an empirical character and is based on an inspection of the regular exceptional graphs.

In fact, the Hoffman bound is attained for a regular graph G if and only if G has a $(0, \tau)$ -regular set such that $\tau = -\lambda_n$. The necessary condition was proved in [1] (see also [11]) and the sufficient condition was proved in [2]. The following theorem stems from [10].

Theorem 3.1. *Let G be an r -regular graph and $\lambda_n = -\tau$ its least eigenvalue. For any stable set S of size s and characteristic vector \mathbf{z} , we have:*

$$s \leq \frac{n\tau}{r + \tau}.$$

Furthermore, the following are equivalent:

- (i) *Equality holds.*
- (ii) *\mathbf{z} is a linear combination of a r -eigenvector and a λ_n -eigenvector.*
- (iii) *The bipartite subgraph induced by the partition $\{S, V(G) \setminus S\}$ is semi-regular.*
- (iv) *The partition $\{S, V(G) \setminus S\}$ is equitable.*

It is easy to prove that the stability number of regular exceptional graphs from the first layer is 3 or 4, in the 2nd layer is 2 or 3, and in the 3rd layer is 2. In fact, if S is a maximum stable set of an r -regular graph G , then

$$n - \alpha(G) = \left| \bigcup_{i \in S} N_G(i) \right| \leq \sum_{i \in S} |N_G(i)| = \alpha(G)r \Rightarrow \alpha(G) \geq \frac{n}{r+1}.$$

Therefore, taking in account the relation between the order n of the regular exceptional graphs and their regularities in each layer, combining the Hoffman upper bound with the above lower bound, the result follows.

However, in spite of some efforts, we were not able to prove theoretically that the Hoffman upper bound is attained in regular exceptional graphs in the 1st and 2nd layer.

We shall construct all regular exceptional graphs from the first and second layer by $(0, 2)$ -extensions. For the first layer the $(0, 2)$ -extension will have size 4 and for the second layer the size is 3. Applications of $(0, 2)$ -extensions will create a stable set of the corresponding size in the resulting graph. This stable set will be a maximum stable set by the Hoffman bound and, from this construction, we may conclude that the Hoffman upper bound is attained for all regular exceptional graphs in the 1st and 2nd layer.

The graphs from the 3rd layer will be considered separately and they will be built by $(1, 3)$ -extensions.

With each type of (κ, τ) -extension we consider the corresponding partial order relation \preceq .

As observed in [2], we may state the following result.

Theorem 3.2. *Regular exceptional graphs are not minimal elements of the posets (\mathcal{L}_1, \preceq) and (\mathcal{L}_2, \preceq) .*

As we shall see the same holds for (\mathcal{L}_3, \preceq) .

Together with $\mathcal{L}_1, \mathcal{L}_2, \mathcal{L}_3$ one can study the posets $\mathcal{E}_1, \mathcal{E}_2, \mathcal{E}_3$ of exceptional graphs from the three layers with corresponding relations \preceq . It would be interesting to study the structure of all these posets. The sets $\mathcal{L}_1, \mathcal{L}_2, \mathcal{L}_3$ are infinite while the sets $\mathcal{E}_1, \mathcal{E}_2, \mathcal{E}_3$ contains 163, 21, 3 elements respectively.

Throughout the recursive construction, starting from a regular exceptional graph G_1 , with least eigenvalue -2 , every regular graph G_i , with $i \geq 2$, obtained by (κ, τ) -extensions and with least eigenvalue -2 , remains an exceptional graph.

This conclusion is a consequence of the fact that the graph property of being a line graph is a hereditary property. This means that any induced subgraph of a line graph is also a line graph. Hence we have the following proposition.

Proposition 3.3. *Let G be a regular graph with least eigenvalue -2 . Let H be a regular induced subgraph of G . We have*

- (i) *if G is a line graph then H is also a line graph,*
- (ii) *if H is an exceptional graph then G is also an exceptional graph.*

3.1. Construction of regular exceptional graphs in the 1st layer by (0, 2)-extensions of size 4. The smallest regular exceptional graphs in the first layer are the five graphs Z_1 , Z_2 , Z_3 , Z_4 and Z_5 of order 10 and degree 3, given in Figure 1 (taken from [9, Appendix A.3]).

Figure 1. The smallest regular exceptional graphs in the 1st layer.

These graphs are obtained by (0, 2)-extensions of the graph $3K_2$ of order 6 and regularity 1, which is a line graph.

The 8 exceptional graphs of order 12 and regularity 4, are obtained by (0, 2)-extensions of graphs of order 8 and regularity 2, that is, one of the three graphs $2C_4$, $C_3 \dot{\cup} C_5$ (disjoint union of graphs C_3 and C_5) or C_8 , which are also line graphs.

Since for regular exceptional graphs of the first layer $r = \frac{n}{2} - 2$, with $10 \leq n \leq 28$, in order to build the Hasse diagram of the first layer partially ordered by the relation \preceq , this set of exceptional graphs is divided into two partially ordered subsets: the graphs with even regularity, obtained by (0, 2)-extensions from a graph with even regularity, and the graphs with odd regularity, obtained by (0, 2)-extensions from a graph with odd regularity.

If G is a graph of even order n and regularity $r = \frac{n}{2} - 2$ and H is the 0-regular graph of order 4, the adjacency matrix of the graph G' of order $n' = 4 + n$ and regularity $r' = \frac{4+n}{2} - 2 = \frac{n}{2}$ obtained from a graph G by a (0, 2)-extension is given by

$$A_{G'} = \begin{bmatrix} O_4 & B \\ B^T & A_G \end{bmatrix},$$

where O_4 is the adjacency matrix of the graph H , that is, the null square matrix of order 4, A_G is the adjacency matrix of G and B is a matrix with 4 rows and n columns.

Assuming as a known fact that in the case of regular exceptional graphs of the 1st and 2nd layers, the Hoffman upper bound is attained all these graphs can be constructed by extending graphs with additional 4 or 3 vertices in the way implied by the above considerations.

Let us describe $(0, 2)$ -extensions of size 4 in some detail.

The graph G is extended by 4 vertices which form a set $S = V(H)$. Let 1, 2, 3, 4 be the vertices of S . Each vertex of G should become adjacent to exactly two vertices of S . Let us define an r -regular multigraph $M(S)$ having the set S as the vertex set. If a vertex v of G becomes adjacent to vertices x, y of S , then there is an edge labelled v between x and y in $M(S)$. In this way, the vertices of G subdivide the edges of $M(S)$. There are six 2-element subsets of S . Constructing G' from G by an $(0, 2)$ -extension means, in fact, to partition the vertex set of G into six subsets which, in turn, should be assigned to 2-element subsets of S in such a way that $M(S)$ is regular of degree r . However, the resulting graph G' need not to be an \mathcal{L} -graph, and this should be checked in the actual constructions.

A multigraph $M(S)$ can be associated with a weighted complete graph on the four vertices of S (see Fig. 2). The weight x_i on the i -th edge of the multigraph $M(S)$ represents the number of vertices of G adjacent to corresponding vertices in S .

Figure 2. A weighted complete graph with vertex set $\{1, 2, 3, 4\}$.

We have $x_1 + x_2 + x_3 = n/2$ since this is the degree of 1 in $M(S)$. Hence, $x_4 + x_5 + x_6 = n/2$. We can conclude that the sum of weights of the edges of any star $K_{1,3}$ and of any triangle K_3 is equal to $n/2$. In addition, we have $x_1 = x_6$, $x_2 = x_5$ and $x_3 = x_4$.

Because of automorphisms it is sufficient to consider partitions of the vertex set of G determined by the weights x_1, x_2, x_3 with $0 \leq x_1 \leq x_2 \leq x_3 \leq n/2$.

Now we shall propose an algorithm to construct the 163 graphs of the first layer by $(0, 2)$ -extensions which produce equitable partitions.

For a given n construct all feasible triplets (x_1, x_2, x_3) . For each triplet (x_1, x_2, x_3) we find in turn all ordered partitions of the vertex set of G into parts of cardinalities x_1, x_2, \dots, x_6 . For each such partition we consider all graphs G and extend them to a graph G' according to this partition. Then, for every graph G' we calculate the least eigenvalue and if it is equal to -2 we have generated a regular exceptional graph on $n + 4$ vertices. Finally, we should eliminate isomorphic duplicates but record all graph pairs which are in relation \preceq .

A suitable computer program based on the above procedure has generated all 163 regular exceptional graph in the first layer. The results are given in the Appendix where for each graph the list of its immediate successors in the poset \mathcal{L} is given.

3.2. Construction of regular exceptional graphs in the 2nd layer by $(0, 2)$ -extensions of size 3. Using the procedure of construction by (κ, τ) -extensions described in Section 2, our aim is now to build a set of regular graphs obtained by a $(0, 2)$ -extension, $H \oplus G$, such that G is a r -regular graph of order n , with $r = \frac{2n}{3} - 2$, and H is the 0-regular graph of order $|V(H)| = 3$. Therefore, this set includes the regular exceptional graphs of the 2nd layer.

The regular exceptional graphs of the 2nd layer of the lowest order are the graphs of order 9 and regularity 4 in Fig. 3. These graphs are obtained by a $(0, 2)$ -extension of the 2-regular graph C_6 and the disconnected graph $2K_3$, which are line graphs. To construct the Hasse diagram that represents the partially ordered set \mathcal{E}_2 with relation \preceq of the regular exceptional graphs in the second layer, we consider the r -regular graphs of order n , with $r = \frac{2n}{3} - 2$ and $6 \leq n \leq 27$.

Figure 3. The smallest regular exceptional graphs in the 2nd layer.

In fact, in order to construct each adjacency matrix of the graph G' , obtained from G by a $(0, 2)$ -extension, $G' = H \oplus G$, it is necessary to determine the incidence matrix with 3 rows and n columns.

Thus, in order to construct the graphs of the second layer we developed an algorithm similar to the algorithm described in the case of graphs from the first layer. The results are given in Appendix. The Hasse diagram of graphs from the second layer is given in Fig. 4.

Figure 4. Hasse diagram of graphs from the 2nd layer.

3.3. Construction of regular exceptional graphs in the 3rd layer by $(1, 3)$ -extensions of size 4. The exceptional graphs from the 3rd layer are only three. The Hoffman bound is not attained for these graphs. However, it is also possible to build them using the procedure of construction by (κ, τ) -extensions described in Section 2, in this case, by $(1, 3)$ -extensions of size 4.

So, the aim now is to build a set of regular graphs obtained by an $(1, 3)$ -extension, $H \oplus G$, such that G is a r -regular graph of order n , with $r = \frac{4n}{3} - 2$, and H is the 1-regular graph of order 4, i.e. $2K_2$.

Starting from the line graph $2K_2$ and extending the graphs in turn by four vertex $(1, 3)$ -regular sets we obtained the exceptional graphs 185, 186 and 187. They have 8, 12 and 16 vertices respectively. Graph 185 is presented in Fig. 5. Graph 187 is the well known Clebsh graph.

4. Computational results

Our algorithm was implemented in Matlab R2009b in order to construct the adjacency matrices of the regular exceptional graphs of the first layer. Similar algorithms were implemented in the cases of the graphs of the second and third layers. The results produced in each layer are described in the Appendix.

The Hasse diagram of the partially ordered set of regular exceptional graphs

Figure 5. The smallest regular exceptional graph in the 3rd layer.

has four components. Two of these components are associated with the first layer of the regular exceptional graphs: one for the graphs with even degree and the other for the graphs with odd degree.

Notice that there are 3 regular exceptional graphs from the first layer that are not obtained by a $(0, 2)$ -extension of the minimal graphs $3K_2$, $2C_4$, $C_3 \cup C_5$, C_8 : the 5-regular exceptional graph 17, which is obtained by a $(0, 2)$ -extension from the disconnected line graph L_1 (see Fig. 6), the 6-regular exceptional graph 56, which is obtained by $(0, 2)$ -extension from the 4-regular line graph L_2 (see Fig. 6) and the 8-regular exceptional graph 134, which is obtained by $(0, 2)$ -extension from the 6-regular line graph L_3 (see the root graph of L_3 in Fig. 7)

Figure 6. The line graphs L_1 and L_2 .

The maximal elements in the first layer are the eight regular exceptional graphs of order 20 (113-117, 119-121), all the regular exceptional graphs with order 22 (135-152), and the three Chang graphs (strongly regular exceptional graphs of order 28).

The third component of the Hasse diagram is associated with the regular exceptional graphs from the second layer (see Fig. 4). The minimal elements are C_6 and $2K_3$ and the maximal elements are the regular exceptional graphs 181 and 184 (the Schläfli graph).

For the third layer there is a minimal graph $2K_2$ and a strongly regular graph, the Clebsch graph, as maximal.

Figure 7. The root graph of the line graph L_3 .

APPENDIX: Extensions of regular exceptional graphs

The data on the 187 regular exceptional graphs are given in Table A3 from the book [9]. These graphs are denoted here by numbers 1 – 187 and these numbers refer to [9]. The graphs are divided into three layers and into smaller groups according to the number of vertices n and the degree r . For each graph the list of regular exceptional graphs obtained by (κ, τ) -extensions is given.

First layer

$$n = 10, \quad r = 3$$
