## Abstract

This manuscript presents a lossless bitplane-based method for compression of microarray images based on expectation pixel values. The method compress each image on a bitplane basis, from the most to the least significant bitplanes, based on arithmetic coding driven by a 3D finite-context models and Expectation-based Bitplane Coding (EBC). It produces an embedded bitstream that allows progressive decoding of the original image. The EBC is a technique where we can select future pixels to create the context template. EBC alone is not effective to compress microarray images, therefore, we decided to use an hybrid approach using EBC, intra-plane and inter-plane to create a more suitable context template. EBC is more efficient for compressing the least significant bitplanes where the expected values are close to the pixels true values. The results obtained with the proposed method are slightly better in some cases however, generally, they are very similar.

## 1 Introduction

The raw data resulting from a microarray experiment consist of a pair of 16 bits per pixels of grayscale images (see Figure 1). These images, depend on the size of the array and the resolution of the scanner, and may require tens of megabytes to be stored or transmitted without any compression loss. Due to this fact, and the need for long-term storage and efficient transmission, the development of lossless compression methods with progressive decoding capabilities is an important challenge. In the literature, we can find several proposals for lossless compression of microarray images [2, 3, 5, 6, 7]. The method proposed by Neves *et al.* [6], which uses a 3D finite-context model and arithmetic coding, is the one of the most promising approaches. The main idea of the proposed method is to use EBC instead of intra-plane coding, in each bitplane where EBC provides best compression results compared to intra-plane coding.

Figure 1: Example of a pair of images ( $1041 \times 1044$  pixels) that results from a microarray experiment.

## 2 Expectation-based Bitplane Coding (EBC)

Kikuchi *et al.* [4] proposed recently the idea of EBC. This approach can be useful in some bitplanes, where the neighbors bits are not so meaningful as they seem. Sometimes, the neighboring bits are only refining bits that fine-tune the value of that particular pixel. In 2010, Chen *et al.* [1] proposed a lossless compression algorithm that uses EBC. Our proposal uses a similar approach that can be applied to microarray images. Suppose  $p = \{p_{15}, p_{14}, \dots, p_2, p_1, p_0\}$ , where  $p_i$  is the value of the pixel  $p_i$  at bitplane  $i$ . When we are encoding the  $n^{\text{th}}$  bitplane, if the pixel  $p$  is already encoded at the current bitplane, its expectation value is formulated as

$$E(x) = \sum_{i=n}^{15} 2^i + (2^{n-1} - 1). \quad (1)$$

On the other hand, if the pixel  $p$  has not been encoded at current bitplane, its expectation value is defined as:

$$E(x) = \sum_{i=n}^{15} 2^i + (2^n - 1). \quad (2)$$

During the compression process, we use this expectation values instead of the real bit values only when the EBC is more efficient to compress the pixels of the current bitplane. In case of using the EBC, if the expected value of the context is lower than the expected value of the current pixel, the context bit used is 0, otherwise 1 is used. The variable size template used is described in Figure 2 and as we can see, there are two future pixels (pixels 4 and 3) that are used in the context template. The pixel denoted by 0 represents the current pixel being compressed. Using this approach, we can select future pixels for the context template, which is more efficient for the least significant bitplanes, where the neighboring bits of each bitplane are merely refining bits and they only fine-tune the final value of that particular pixel.

## 3 Algorithm

The compression algorithm is based on simple bitplane separation, where each binary layer (from the least to the most significant one) is then compressed using 3D finite-context models and arithmetic coding. In Figure 3, we can see an example of a 3D context configuration used to compress a microarray image. As we can see, there is inter-plane and intra-plane pixels that can be used in the context template. However, in our approach, we decided to keep the inter-plane configuration that is used in [6] and try to use intra-plane and EBC competing with each other. In each bitplane, we use inter-plane + EBC or inter-plane + intra-plane, depending which one saves more bits. The selected approach must be sent as side information to the decoder in order to be possible to decode the original image correctly. This only requires 16 extra bits, which is a small cost to pay compared to the image compression data.

Figure 3: 3D context configuration [6].

## 4 Results and conclusions

The microarray images used in the experimental results were collected from three publicly available sources. 1) 32 images that we refer to as the APO\_AI set; 2) 14 images forming the ISREC set; 3) three images previously used in MicroZip. The image sizes ranges from  $1000 \times 1000$  to  $5496 \times 1956$  pixels and all of them have 16 bits per pixel. The average results presented take into account the different sizes of the images, i.e., they correspond to the total number of bits divided by the total number of image pixels. In Table 1, we have the compression results for the algorithm proposed in [6] and our approach. As we can see, there are small improvements in some images but, generally, the results are very similar. Furthermore, we noticed that, in the last 8 least significant bitplanes, our approach uses more times EBC instead of intra-coding, which leads to the conclusion that EBC is more effective to compress the least significant bitplanes than intra-coding (see Fig. 4). It is possible to conclude that in the least significant bitplanes, the algorithm actually generates better results. As future work, it will be interesting to explore other alternatives to EBC or using a different equation to obtain the expected value.

Figure 4: Percentage of utilization of each context (INTRA vs EBC) for each plane, from the least significant bitplane (0) to the most significant one (15).
