

OAuth 2.0 authorization framework

Goal

- ▷ Allow an application to access user resources maintained by a service/server

Roles (RFC 6749)

▷ Resource owner

- ♦ An entity capable of **granting access** to a **protected resource**
- ♦ **End-user**: a resource owner that is a person

▷ Resource server

- ♦ The server hosting protected resources
- ♦ Capable of accepting and responding to protected resource requests using **access tokens**

Roles (RFC 6749)

▷ Client

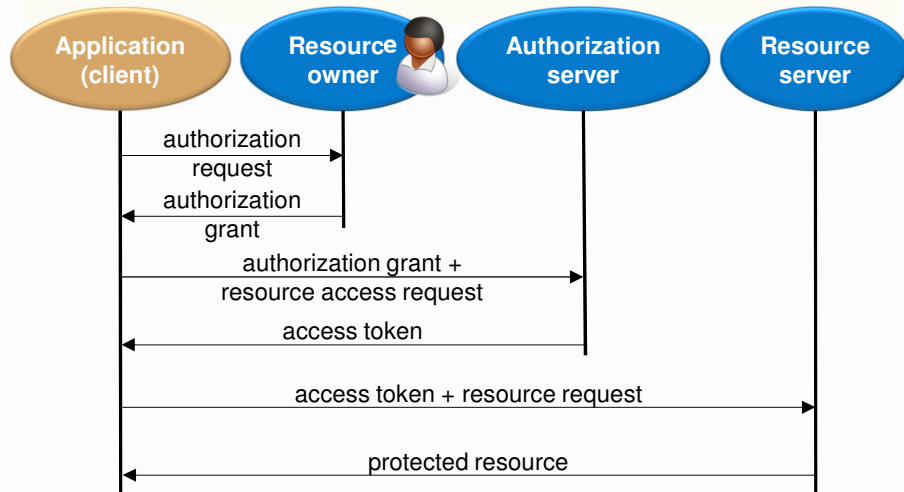

- ♦ An **application** making requests for protected resources on behalf of the resource owner and with its authorization

▷ Authorization server (aka OAuth server or provider)

- ♦ The server issuing **access tokens** to the client after successfully **authenticating** the resource owner and obtaining its **authorization** for the client to access one of its resources

Identification, Authentication and Authorization

6

Communication endpoints: Authorization endpoint

- ▷ Service provided by the OAuth server
 - ♦ Authenticates the resource owner
 - ♦ Asks for the delegation of access rights to its protected resources to the client
 - ♦ Send an authorization grant to the redirection endpoint

Communication endpoints: Token endpoint

- ▷ Service provided by the OAuth server
 - ♦ Produces access tokens given an authorization grant
 - ♦ It can also produce refresh tokens
 - ♦ Refresh tokens can be used to get new tokens
 - With an authorization grant
- ▷ Client authentication
 - ♦ ClientID + ClientSecret + HTTP basic authentication

Communication endpoints: Redirect endpoint

- ▷ Service provided by the client
 - ♦ It collects the authorization grant provided by the OAuth server
 - ♦ It should be called by the OAuth server using an HTTP redirect

Application (client) types

- ▷ Type is related with the ability to maintain the confidentiality of client credentials
 - ♦ Even from the resource owner
- ▷ Confidential
 - ♦ Capable
 - ♦ e.g. a secure server
- ▷ Public
 - ♦ Incapable
 - ♦ e.g. a web browser-based application, a mobile App

Application (client) profiles

- ▷ Web application
 - ♦ Confidential client running on a web server
- ▷ User-agent based application
 - ♦ Public client where the client code runs on a user-agent application (e.g. a browser)
- ▷ Native application
 - ♦ Public client installed and executed on the device used by the resource owner

Application (client) registration (in an OAuth server)

- ▷ Clients accessing OAuth servers must be previously registered
 - ♦ Nevertheless, the standard does not exclude unregistered clients
 - ♦ A registered client is given a unique identifier
 - ClientID
- ▷ Registration includes both informational, legal and operational information
 - ♦ Redirection URLs
 - ♦ Acceptance of legal terms
 - ♦ Application (client) name, logo, web site, description
 - ♦ Client type
 - ♦ Client authentication method (for confidential clients)

OAuth tokens: Authorization grant

- ▷ Created by an OAuth server
 - ♦ Upon authenticating a resource owner and getting its consent to grant access to a protected resource
 - ♦ An opaque byte blob that makes sense only to its issuer
- ▷ Short validity time
 - ♦ Just enough to get an access token

OAuth tokens: Access token

- ▷ Created by an OAuth server
 - ♦ Upon authenticating a client and receiving an authorization grant
 - ♦ An opaque byte blob that makes sense to its issuer and to the resource owner
 - An access capability
- ▷ Bearer tokens
 - ♦ Clients need to protect their use with HTTPS
 - ♦ Clients can handover tokens to others

OAuth tokens: Refresh token

- ▷ Created by an OAuth server
 - ♦ When creating an access token
 - ♦ An opaque byte blob that makes sense only to its issuer
 - ♦ It can be used to collect a new access token
 - Still requiring the client authentication
- ▷ Bearer tokens
 - ♦ Clients need to protect their use with HTTPS
 - ♦ Clients can handover tokens to others

OAuth flows

- ▷ Authorization code flow
 - ♦ 3-legged OAuth
 - ♦ Default OAuth flow
 - ♦ The most secure
- ▷ Implicit flow
- ▷ Resource owner password credentials flow
- ▷ Client credentials flow
 - ♦ 2-legged flow

Authorization code flow

- ▷ 3-legged OAuth
 - ♦ It enables checking the identity of the three involved actors
- ▷ OAuth server authenticates the resource owner
 - ♦ Username + password or other means
- ▷ OAuth server authenticates the client
 - ♦ ClientID + ClientSecret + HTTP basic authorization
- ▷ Client authenticates the OAuth server
 - ♦ Certificate + URL

Authorization code flow

- ▷ Requirements
 - ♦ Confidential application types
 - ♦ Secure storage for tokens, ClientID and ClientSecret
- ▷ Setup
 - ♦ Client registration in the OAuth server
 - Client receives ClientID and ClientSecret
 - Not regulated by OAuth

Authorization code flow

- ▷ Resource owner uses a server-based Web App
 - ♦ The client
- ▷ The client uses the resource server API to get a resource
 - ♦ The resource server redirects the client to the OAuth server
- ▷ The OAuth server authenticates the resource owner
 - ♦ And sends an authorization grant to the client
- ▷ The client gets an access token from the OAuth server
 - ♦ Using its credentials (to have access permission)
 - ♦ Using its authorization grant
- ▷ The client uses again the resource server API to get a resource
 - ♦ This time providing an access token

Implicit flow

- ▷ Requirements
 - ♦ Public application types
- ▷ Setup
 - ♦ Client registration in the OAuth server
 - Client receives ClientID
 - Not regulated by OAuth
- ▷ Limitations
 - ♦ No client authentication
 - ♦ No refresh tokens

Implicit flow

- ▷ Resource owner uses a mobile or client-based Web App
 - ♦ The client
- ▷ The client uses the resource server API to get a resource
 - ♦ The resource server redirects the client to the OAuth server
- ▷ The OAuth server authenticates the resource owner
 - ♦ And sends an access token to the client
- ▷ The client uses again the resource server API to get a resource
 - ♦ This time providing an access token

Resource owner password flow

- ▷ Requirements
 - ♦ Confidential application types
 - ♦ Sharing of resource owner credentials with client applications
 - ♦ Secure storage for tokens, ClientID and ClientSecret
- ▷ Setup
 - ♦ Client registration in the OAuth server
 - Client receives ClientID and ClientSecret
 - Not regulated by OAuth
- ▷ Limitations
 - ♦ Resource owners need to trust on client applications

Resource owner password flow

- ▷ Resource owner uses a server-based Web App
 - ♦ The client
- ▷ The client uses the resource server API to get a resource
 - ♦ The resource server requests a token
- ▷ The client asks the resource owner for authentication credentials
- ▷ The client gets an access token from the OAuth server
 - ♦ Using its credentials (to have access permission)
 - ♦ Using the resource owner's credentials
 - ♦ These should be immediately discarded
- ▷ The client uses again the resource server API to get a resource
 - ♦ This time providing an access token

Client credentials flow

- ▷ Requirements
 - ♦ Confidential application types
 - ♦ Secure storage for tokens, ClientID and ClientSecret
- ▷ Setup
 - ♦ Client registration in the OAuth server
 - Client receives ClientID and ClientSecret
 - Not regulated by OAuth
- ▷ Limitations
 - ♦ No resource owner authentications or authorizations

Client credentials flow

- ▷ Resource owner uses a server-based Web App
 - ♦ The client
- ▷ The client uses the resource server API to get a resource
 - ♦ The resource server requests a token
- ▷ The client gets an access token from the OAuth server
 - ♦ Using its credentials (to have access permission)
- ▷ The client uses again the resource server API to get a resource
 - ♦ This time providing an access token
